Task 1: Array Storage (15 points)

The task was to write various functions and structures in order to store and fetch from a 2D byte array. The task also stated that a 1D char* array was to be used to emulate an 2D array in C.

Step 1
The function two_d_alloc takes in number of rows, columns and the element size in order to allocate enough memory using malloc for each slot in the array. (Codeline 4).

Step 2
The function two_d_dealloc deallocates the the array by using free(). (Codeline 24)
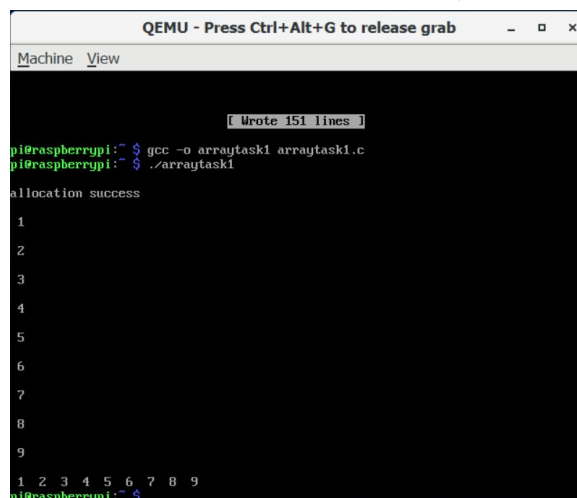

Step 3
Check main() at codeline 139.

Step 4
The function two_d_store takes in the array, the row and column which the new value is to be stored, the matrix size and the size of each arrayslot. The position of the value in the matrix will be converted via ColumnMax*Row+Column to get the right position in the 1D array. (Codeline 29)

Step 5
The function two_d_fetch takes in the array, column and row number, it also takes in the size of each element and the amount of columns and rows the matrix has in total in order to be able to calculate position. It then takes out the value that is stored in that position and returns it.

Step 6
The init_loop function runs the store and fetch on a 3x3 matrix. (Codeline 92)

Step 7

In order to counteract problems the store and fetch functions has if-statements that checks if the user is trying to store elements outside of the matrix boundaries.

Step 8

Two more functions were written. two_d_store_col (Codeline 66) and two_d_fetch_col (Codeline 69). Another initialization loop (init_loop_col Codeline 115) was written to check that everything works as intended. As seen on the bottom row (elements printed in order of the array) we can see that the printout follows the column major format.

Step 9

The function arguments and return values were adjusted to accommodate memory address instead of taking in and returning the actual value. The functions structure is the same except for that the memory address is used instead of returning actual values.

```
28 . void two_d_store(char *p, int n, int m, int *value, int N, int M, int size){ .
.
.
45 . char* two_d_fetch(char *p,int n,int m, int N, int M, int size){
.
.
95 .     two_d_store(array, 0, 0,((int*)&a), n, m,size);
96 .     two_d_store(array, 1, 0,((int*)&b), n, m,size);
```

Step 10

To make sure that other data types also work with inserting and fetching values from the array each step takes into consideration how big the datatype is. For example if you insert data type int which consists of 4 bytes it jumps 4 bytes instead of just jumping one byte like before.

```c
28 . void two_d_store(char *p, int n, int m, int *value, int N, int M, int size){
29 .     if(n >= N){
30 .             printf("\ndimensions doesnt match\n");
31 .             return;
32 .     }
33 .     if(m >= M){
34 .             printf("\ndimensions doesnt match\n");
35 .             return;
36 .     }
37 .     //printf("Value: %d\n", *value);
38 .     int i;
39 .     for(i = 0;i < size; i++){
40 .             p[(N * m + n)*size + i] = *((char*)value+i);
41 .     }
42 .     return;
43 . }
44 .
45 . char* two_d_fetch(char *p,int n,int m, int N, int M, int size){
46 .     if(n >= N){
47 .             printf("\nElement does not exist\n");
48 .             return;
49 .     }
50 .     if(m >= M){
51 .             printf("\nElement does not exist\n");
52 .             return;
53 .     }
54 .     int position = (N * m + n)*size;
55 .     char *x = p+position;
56 .     //printf("%d ", (int)*x);
57 .     return x;
58 . }
```

```c
1    . #include <stdlib.h>
2    . #include <stdio.h>
3    .
4    . char* two_d_alloc(int N, int M, int size){
5    .
6    .     //allocates an char array with size n*m
7    .     //is acutally an 1D array using buffer
8    .
9    .     char *c_array;
10   .
11   .     //calls malloc to allocate appropriate number of bytes for the array
12   .     c_array = (char *) malloc(size*N*M);
13   .
14   .     if(c_array != NULL){
15   .             printf("\nallocation success\n");
16   .     }
17   .     else{
18   .             printf("\nallocation fail\n");
19   .     }
20   .     return c_array;
21   .
22   . }
23   .
24   . void two_d_dealloc(char *p){
25   .     free(p);
```

```c
26  .    return;
27  . }
28  .
29  . void two_d_store(char *p, int n, int m, int value, int N, int M, int size){
30  .    if(n >= N){
31  .            printf("\ndimensions doesnt match\n");
32  .            return;
33  .    }
34  .    if(m >= M){
35  .            printf("\ndimensions doesnt match\n");
36  .            return;
37  .    }
38  .    p[N * m + n] = value;
39  .    return;
40  . }
41  .
42  . int two_d_fetch(char *p,int n,int m, int N, int M, int size){
43  .    if(n >= N){
44  .            printf("\nelement does not exist\n");
45  .            return;
46  .    }
47  .    if(m >= M){
48  .            printf("\nelement does not exist\n");
49  .            return;
50  .    }
51  .    int x = p[N * (m) + n];

142.      print_matrix(array,n,m);
143.      memory_dump(array, n*m*size);
144.      //loop(array);
145.      return 0;
146. }
```

Task 3: Linked Lists (5 points)

The following task was to implement a struct which holds an element value and a pointer to the next node in the list. The nodes of the struct were then placed in the array in corresponding order. The memory dump shows the address and value in hexadecimal form. As shown below the value and address of every element in the linked list is printed. The address of each element is incremented and judging by what our memory dump has printed out we can see that each node points at the next one and that the last one points at NULL (00000000000000). (Codeline 24)

```c
1  . #include <stdlib.h>
2  . #include <stdio.h>
3  . typedef struct element{
4  .      int value;
5  .      struct element * next;
6  . }node;
7  . void two_d_store(char *p, int n, int m, int *value, int N, int M, int size){
8  .      if(n >= N){
9  .              printf("\ndimensions doesnt match\n");
10 .              return;
11 .      }
12 .      if(m >= M){
13 .              printf("\ndimensions doesnt match\n");
14 .              return;c
15 .      }
16 .      //printf("Value: %d\n", *value);
17 .      int i;
